

# Exceptions and Interrupts

- “Unexpected” events requiring change in flow of control
  - Different ISAs use the terms differently
- Exception
  - Arises within the CPU
    - e.g., undefined opcode, overflow, syscall, ...
- Interrupt
  - From an external I/O controller
- Dealing with them without sacrificing performance is hard

# Handling Exceptions

- In MIPS, exceptions managed by a System Control Coprocessor (CP0)
- Save PC of offending (or interrupted) instruction
  - In MIPS: Exception Program Counter (EPC)
- Save indication of the problem
  - In MIPS: Cause register
  - We'll assume 1-bit
    - 0 for undefined opcode, 1 for overflow
- Jump to handler at 8000 00180

# An Alternate Mechanism

- Vectored Interrupts
  - Handler address determined by the cause
- Example:
  - Undefined opcode:           C000 0000
  - Overflow:                   C000 0020
  - ....:                        C000 0040
- Instructions either
  - Deal with the interrupt, or
  - Jump to real handler

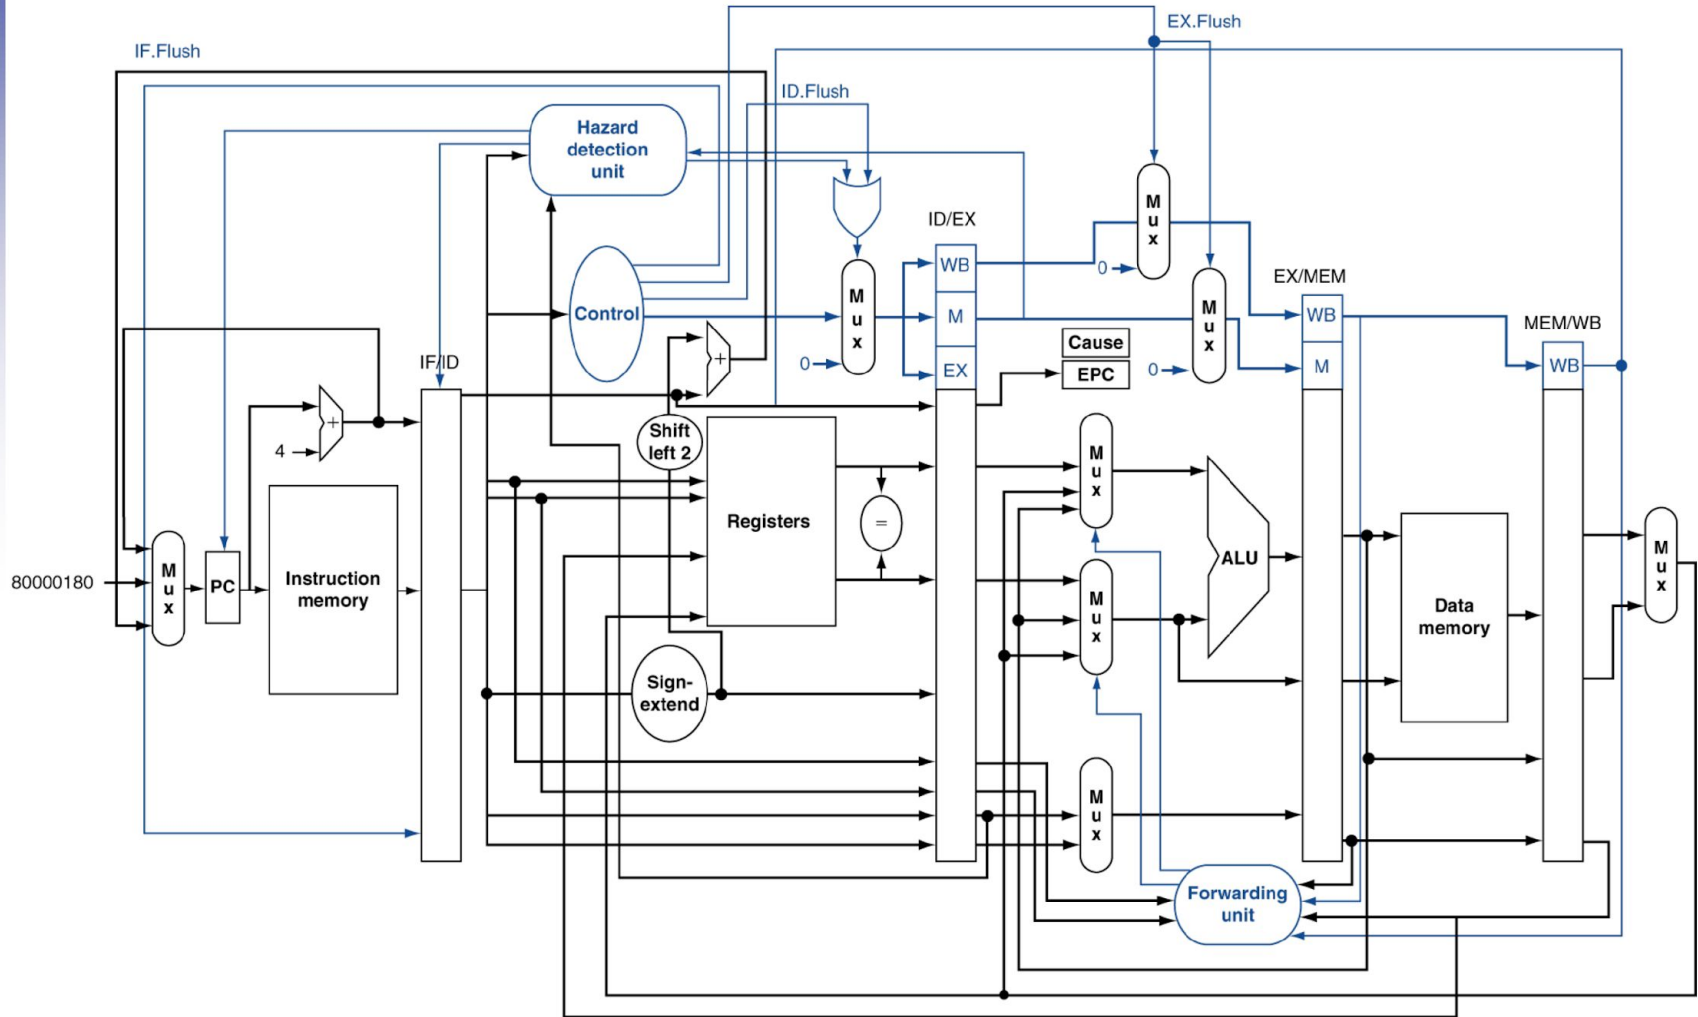

# Handler Actions

- Read cause, and transfer to relevant handler
- Determine action required
- If restartable
  - Take corrective action
  - use EPC to return to program
- Otherwise
  - Terminate program
  - Report error using EPC, cause, ...

# Exceptions in a Pipeline

- Another form of control hazard
- Consider overflow on add in EX stage  
add \$1, \$2, \$1
  - Prevent \$1 from being clobbered
  - Complete previous instructions
  - Flush add and subsequent instructions
  - Set Cause and EPC register values
  - Transfer control to handler
- Similar to mispredicted branch
  - Use much of the same hardware

# Pipeline with Exceptions

# Exception Properties

- Restartable exceptions
  - Pipeline can flush the instruction
  - Handler executes, then returns to the instruction
    - Refetched and executed from scratch
- PC saved in EPC register
  - Identifies causing instruction
  - Actually PC + 4 is saved
    - Handler must adjust

# Exception Example

- Exception on `add` in

40	<code>sub</code>	<code>\$11, \$2, \$4</code>
44	<code>and</code>	<code>\$12, \$2, \$5</code>
48	<code>or</code>	<code>\$13, \$2, \$6</code>
4C	<code>add</code>	<code>\$1, \$2, \$1</code>
50	<code>slt</code>	<code>\$15, \$6, \$7</code>
54	<code>lw</code>	<code>\$16, 50(\$7)</code>

...

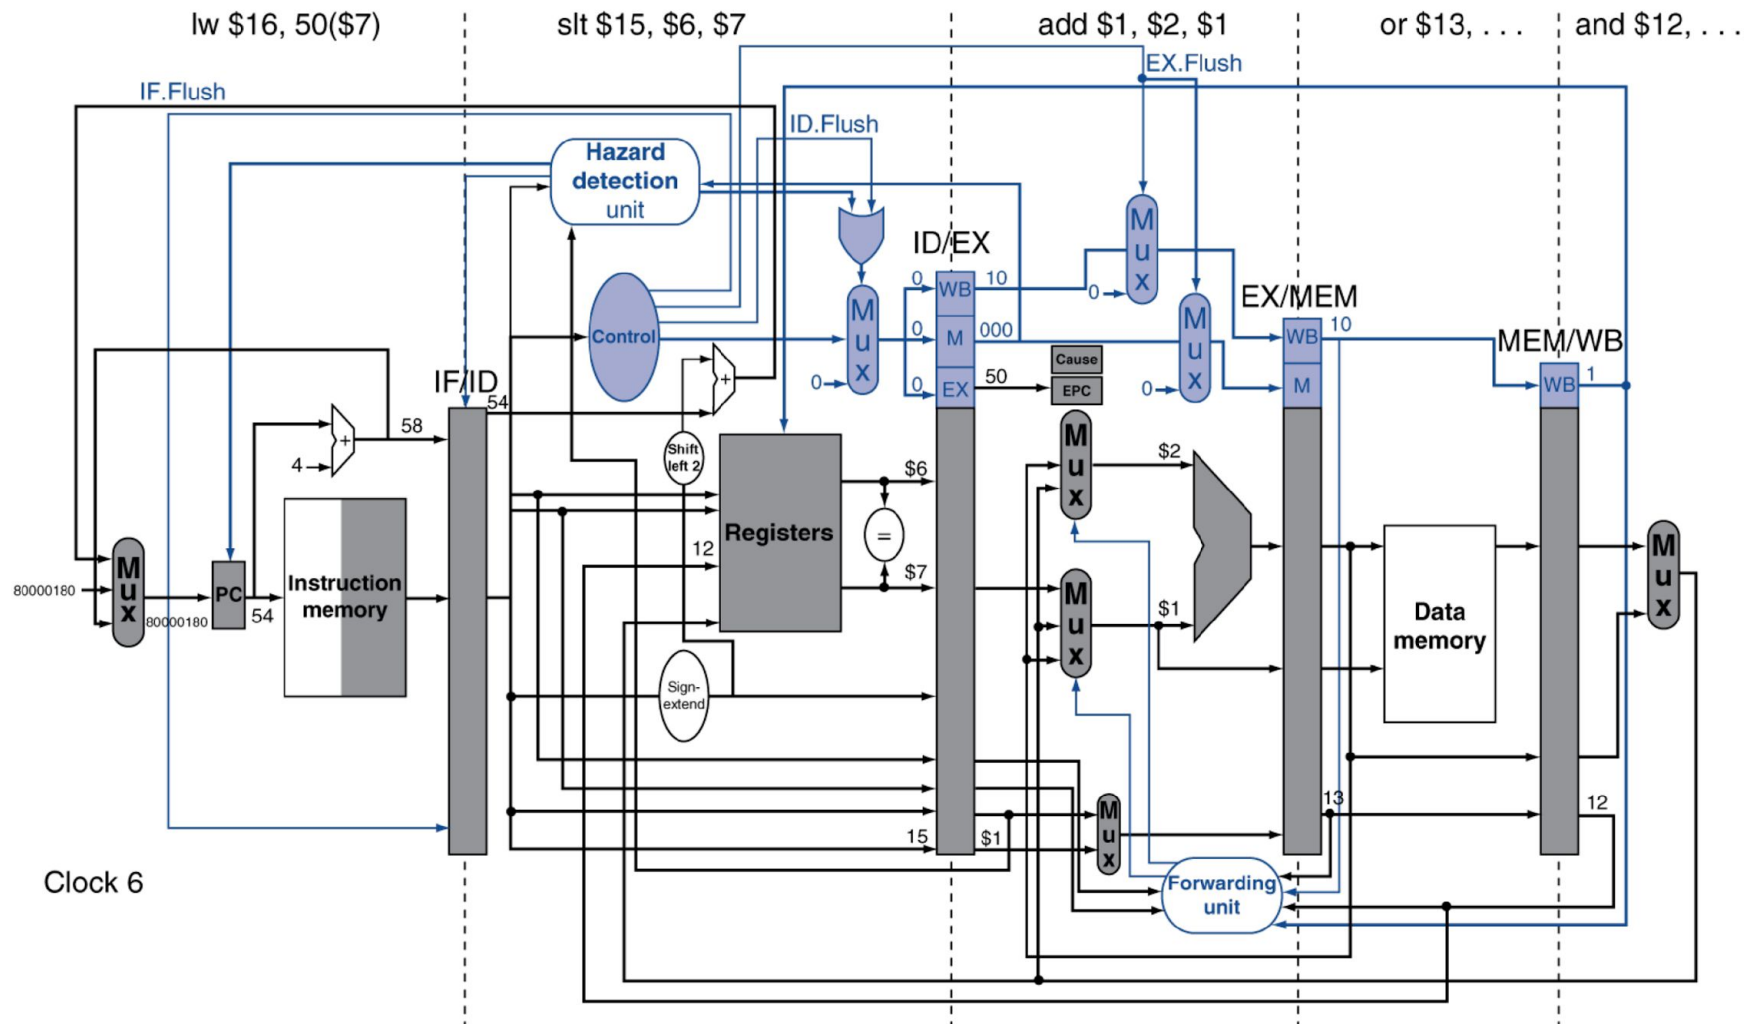

- Handler

80000180	<code>sw</code>	<code>\$25, 1000(\$0)</code>
80000184	<code>sw</code>	<code>\$26, 1004(\$0)</code>

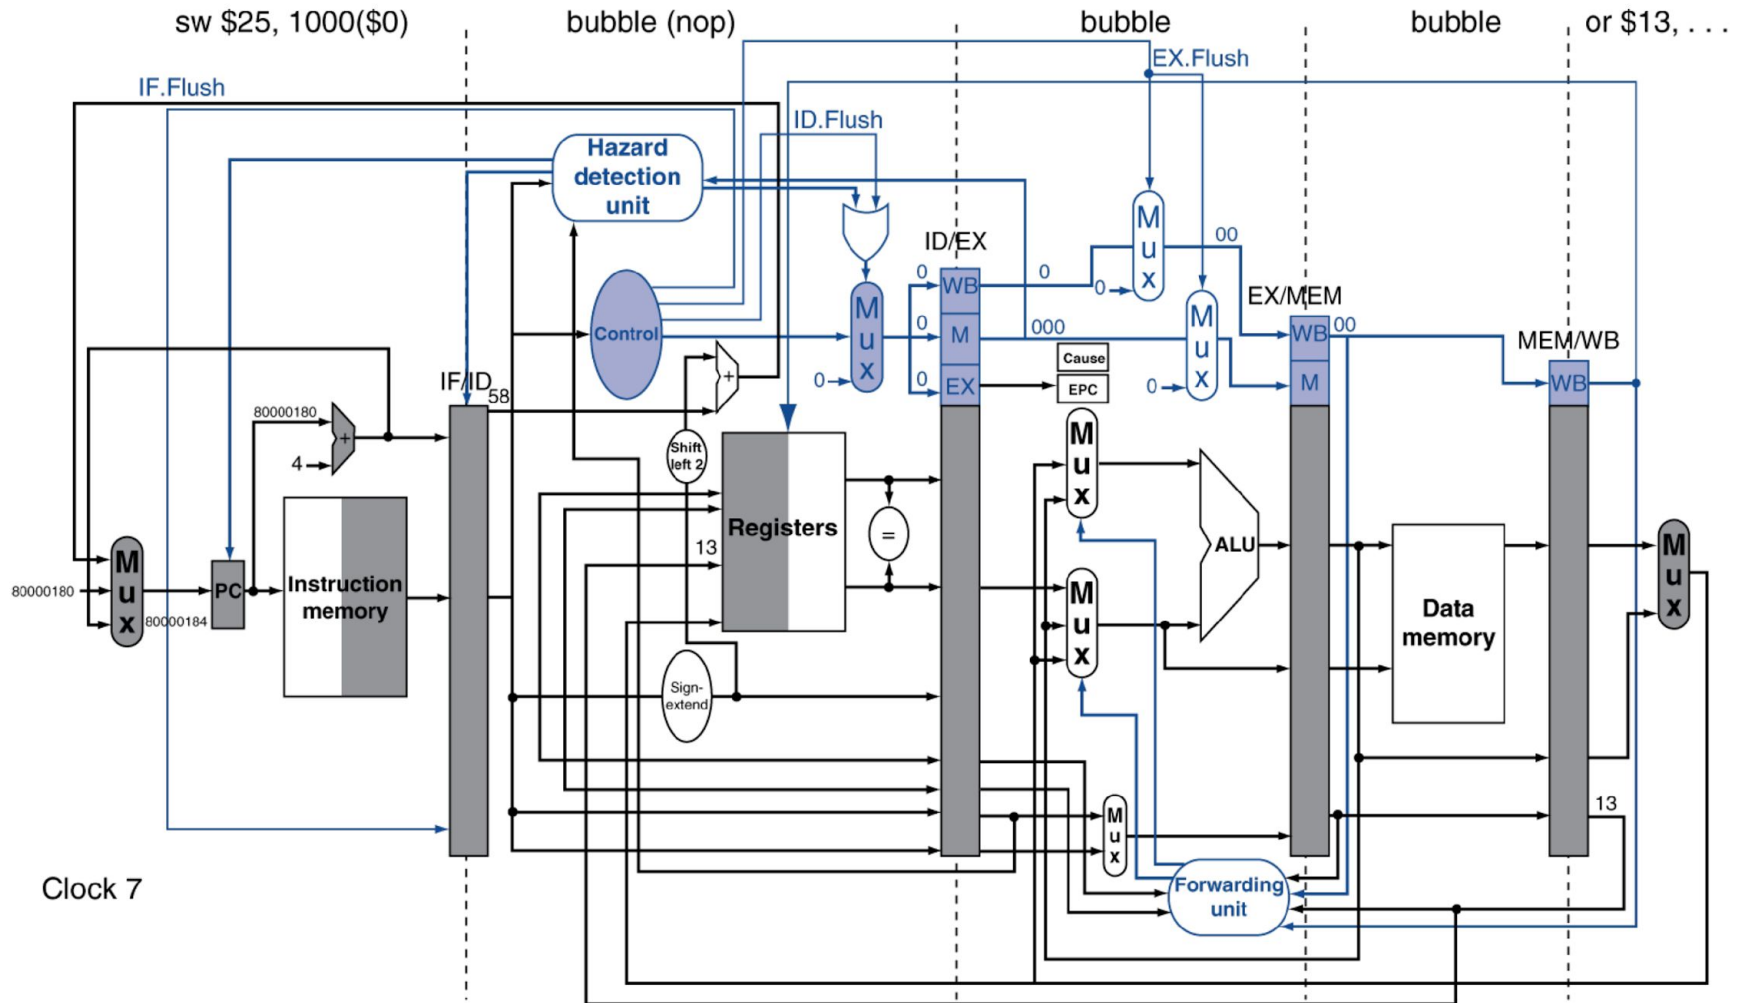

...

# Exception Example

# Exception Example

# Multiple Exceptions

- Pipelining overlaps multiple instructions
  - Could have multiple exceptions at once
- Simple approach: deal with exception from earliest instruction
  - Flush subsequent instructions
  - “Precise” exceptions
- In complex pipelines
  - Multiple instructions issued per cycle
  - Out-of-order completion
  - Maintaining precise exceptions is difficult!
